Given the following Neural Network and input values, compute the output value. Use the sigmoid activation function. Show your work for partial credit.

Input	Level 1 Weights	Level 1 Weights	Bias
i1 = .8	W1 = .2	W5 = .48	B1 = .23
i2 = .3	W2 = .35	W6 = .34	B2 = .41
	W3 = .15		B3 = .5
	W4 = .6		

The work for partial credit is shown in the attached Excel file, but here are screenshots for simplicity.

Answer:

o1 output value is:	0.7361693

Apply PCA to the Diabetes dataset. What are the resulting projections for the top 2 dimensions?

The projections themselves are stored in the attached diabetes_pca_top_2_projections.csv

Nevertheless, here is a plot of the values with component-1 on the X axis and component 2 on the Y axis.

Also of note:

Here are the top 2 components of the Diabetes data set after applying PCA

	preg	plas	pres	skin	insu	mass	pedi	age
PC-1	0.128432	0.393083	0.360003	0.439824	0.435026	0.451941	0.270611	0.198027
PC-2	0.593786	0.174029	0.183892	-0.331965	-0.250781	-0.100960	-0.122069	0.620589

For component 1 the percentage of the variance explained is: 26.18% For component 2 the percentage of the variance explained is: 21.64% Apply LDA and PCA to the iris dataset. Using the top 2 dimensions, graph the resulting subspace and include the graphs here. Which one produces a better separation between classes.

LDA provides a better separation between the classes. This is illustrated by noting how many of the dots shown in green "bleed" into the yellow class with PDA whereas there is almost no intermixing with LDA
